• Helps reduce energy consumption
• Allows for tailored custom heating solutions
• Allows for fast and controllable process
• Improves product quality through repeatability
• Increases productivity and efficiency
• Is quieter and cleaner than other heating methods
• Requires very low maintenance
• Requires less floor space

• Configurable to your requirements and process
• Power supplies are highly customizable
• Power supply can be placed away from the work area
• Is easy to integrate into a fully automated production
• Single power supply can support different heat processes and applications
• Expert technical and application support
• Customized packaging and solutions for OEM customers

A free application review by our team will help you identify if induction heating is the best solution for you
Send your samples to our lab for testing and analysis
Let us design a custom heating solution with the help of our experienced engineers
A Comparison of Efficiency and Power Consumption for Induction Heating versus other Heating Methods

UltraFlex Power Technologies often has customers who ask about the potential power savings for using Induction over other common heating methods. The following provides a guide for potential power savings that customers may see.

**Heating by Induction has minimal wasted heat, with direct transfer of energy to the part being heated. This high efficiency results in significant power savings.**

1. A 1998 study conducted by Lawrence Berkeley National Laboratory for the Department of Energy, found induction cooktops to transfer 84% of the power to the load vs. only 71% for electric coils and 40% for gas.

- **Type of Heating Element** | **Efficiency Factor**
  - Electric – Induction | 84.00%
  - Electric – Radiant* | 71.00%
  - Gas | 40.00%

*Efficiency Chart Source: US Department of Energy (1998)*

*Electric radiant efficiency varies depending on size of heating element relative to part size. If the element is larger than the part to get sufficient power, the efficiency will be much less.*

2. If we “normalize” the above data, to show delivered power of 1.0 kW for all methods, we see the difference in required input power. We can then easily calculate the power savings of other Induction vs Electric and Gas.

<table>
<thead>
<tr>
<th>Examples Stated Power vs. Delivered Power</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Induction*</td>
</tr>
<tr>
<td>Electric – Radiant</td>
</tr>
<tr>
<td>Gas</td>
</tr>
</tbody>
</table>

* Into a magnetic steel load below curie.

3. For batch heating processes, the efficiency can be even greater since you only spend energy with Induction Heating when you need to heat. There is no wasted energy with Induction Heating versus keeping furnaces and ovens running or delays in pre-heating ovens.

<table>
<thead>
<tr>
<th>Required Input Power for 1.0 kW Delivered Power and Associated Power Savings</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Type</strong></td>
</tr>
<tr>
<td>Induction</td>
</tr>
<tr>
<td>Electric – Radiant</td>
</tr>
<tr>
<td>Gas</td>
</tr>
</tbody>
</table>

4. UltraFlex’s testing and research is comparable to these results. Below is our more conservative estimate of the efficiency of power delivered to the desired load vs. heat transferred to other parts and environment for a variety of heating methods.
